一、数据字典列表接口

根据element组件要求,返回列表数据必须包含hasChildren字典,如图:

https://element.eleme.cn/#/zh-CN/component/table

~ 2016-05-01	王小虎	上海市普陀区金沙江路 1519 弄
2016-05-01	王小虎	上海市普陀区金沙江路 1519 弄
2016-05-01	王小虎	上海市普陀区金沙江路 1519 弄
2016-05-03	王小虎	上海市普陀区金沙江路 1516 弄

支持树类型的数据的显示。当 row 中包含 children 字段时,被视为树形数据。渲染树形数据时,必须要指定 row-key 。支持子节点数据异步加载。设置 Table 的 lazy 属性为 true 与加载函数 load 。通过指定 row 中的 hasChildren 字段来指定哪些行是包含子节点。 children 与 hasChildren 都可以通过 tree-props 配置。

1、model模块添加数据字典实体

```
1 @Data
 2 @ApiModel(description = "数据字典")
 3 @TableName("dict")
4 public class Dict {
5
6
      private static final long serialVersionUID = 1L;
 7
      @ApiModelProperty(value = "id")
8
      private Long id;
9
10
11
      @ApiModelProperty(value = "创建时间")
      @JsonFormat(pattern = "yyyy-MM-dd HH:mm:ss")
12
```

```
13
       @TableField("create_time")
14
       private Date createTime;
15
       @ApiModelProperty(value = "更新时间")
16
       @TableField("update_time")
17
       private Date updateTime;
18
19
       @ApiModelProperty(value = "逻辑删除(1:已删除, 0:未删除)")
20
       @TableLogic
21
       @TableField("is_deleted")
22
23
       private Integer isDeleted;
24
       @ApiModelProperty(value = "其他参数")
25
       @TableField(exist = false)
26
       private Map<String,Object> param = new HashMap<>();
27
28
       @ApiModelProperty(value = "上级id")
29
30
       @TableField("parent_id")
       private Long parentId;
31
32
33
       @ApiModelProperty(value = "名称")
34
       @TableField("name")
35
       private String name;
36
37
       @ApiModelProperty(value = "值")
       @TableField("value")
38
39
       private String value;
40
       @ApiModelProperty(value = "编码")
41
       @TableField("dict_code")
42
       private String dictCode;
43
44
       @ApiModelProperty(value = "是否包含子节点")
45
       @TableField(exist = false)
46
       private boolean hasChildren;
47
48
49 }
```

说明: hasChildren为树形组件所需字典,标识为数据库表不存在该字段

2、添加数据字典mapper

```
public interface DictMapper extends BaseMapper<Dict> {
}
```

3、添加数据字典service

```
public interface DictService extends IService<Dict> {
 2
      //根据数据id查询子数据列表
      List<Dict> findChlidData(Long id);
 3
4 }
5
 6 @Service
7
  public class DictServiceImpl extends ServiceImpl<DictMapper, Dict> implements DictSer
8
      //根据数据id查询子数据列表
      @Override
9
      public List<Dict> findChlidData(Long id) {
10
11
           QueryWrapper<Dict> wrapper = new QueryWrapper<>();
12
          wrapper.eq("parent_id",id);
           List<Dict> dictList = baseMapper.selectList(wrapper);
13
          //向list集合每个dict对象中设置hasChildren
14
          for (Dict dict:dictList) {
15
              Long dictId = dict.getId();
16
              boolean isChild = this.isChildren(dictId);
17
18
              dict.setHasChildren(isChild);
           }
19
20
           return dictList;
21
22
      //判断id下面是否有子节点
23
      private boolean isChildren(Long id) {
           QueryWrapper<Dict> wrapper = new QueryWrapper<>();
24
25
          wrapper.eq("parent_id",id);
          Integer count = baseMapper.selectCount(wrapper);
26
          return count>0;
27
28
      }
29 }
```

4、添加数据字典controller

```
1 @Api(description = "数据字典接口")
 2 @RestController
 3 @RequestMapping("/admin/cmn/dict")
 4 @CrossOrigin
 5 public class DictController {
 6
 7
       @Autowired
       private DictService dictService;
 8
 9
       //根据数据id查询子数据列表
10
       @ApiOperation(value = "根据数据id查询子数据列表")
11
       @GetMapping("findChildData/{id}")
12
       public R findChildData(@PathVariable Long id) {
13
           List<Dict> list = dictService.findChlidData(id);
14
          return R.ok().data("list",list);
15
       }
16
17 }
```

二、数据字典列表前端

1、添加数据字典路由

修改router/index.js文件

```
{
 1
 2
       path: '/cmn',
 3
       component: Layout,
 4
       redirect: '/cmn/list',
       name: '数据管理',
 5
 6
       alwaysShow: true,
 7
       meta: { title: '数据管理', icon: 'example' },
       children: [
 8
9
         {
           path: 'list',
10
           name: '数据字典',
11
           component: () => import('@/views/dict/list'),
12
           meta: { title: '数据字典', icon: 'table' }
13
14
         }
       ]
15
16
     },
```

2、定义数据字典列表接口

创建文件 src/api/yygh/dict.js

```
import request from '@/utils/request'
export default {

dictList(id) {//数据字典列表

return request ({

url: `/admin/cmn/dict/findChildData/${id}`,

method: 'get'

})

}
```

3、在dict/list.vue调用

```
1 <script>
 2 import dict from '@/api/yygh/dict'
 3 export default {
       data() {
 4
 5
           return {
               list:[] //数据字典列表数组
 6
 7
           }
8
       },
9
       created() {
           this.getDictList(1)
10
11
       },
       methods: {
12
           //数据字典列表
13
           getDictList(id) {
14
               dict.dictList(id)
15
                   .then(response => {
16
17
                       this.list = response.data.list
                   })
18
19
           },
           load(tree, treeNode, resolve) {
20
               dict.dictList(tree.id).then(response => {
21
```

4、页面数据渲染

修改dict/list.vue页面

```
1 <template>
 2
       <div class="app-container">
 3
       <el-table
           :data="list"
 4
 5
           style="width: 100%"
           row-key="id"
 6
 7
           border
 8
           lazy
           :load="load"
9
           :tree-props="{children: 'children', hasChildren: 'hasChildren'}">
10
11
           <el-table-column
12
           prop="name"
13
14
           label="名称"
           width="150">
15
           </el-table-column>
16
17
           <el-table-column
18
19
           prop="dictCode"
           label="编码"
20
           width="150">
21
22
           </el-table-column>
23
24
           <el-table-column
25
           prop="value"
           label="值"
26
           width="150">
27
           </el-table-column>
28
29
30
           <el-table-column
```
